Final-ABS

Introduction:

After looking through the questions, we decided that in the time given, we should focus on building a model that can predict q106, which asks if the respondent thinks equal treatment of citizens by their government has gotten better or worse. We believe this question is important in order to compare how different respondents have viewed trends towards a "better" government system in their country. For instance, it's possible that a perception of positive trends is strongly correlated with a specific country or demographic group, indicating targeted improvements in equality. Alternatively, if perceptions of unequal treatment are strong correlated with certain groups, these groups may have been disproportionately "left out" of recent progress.

Overall, this analysis could provide grounds for further research into how different groups perceive recent developments around equality in East and Southeast Asia.

EDA:

Before starting our exploratory data analysis, we subsetted the merged Wave 1 data to only include the most important variables as provided in the documentation.

Afterwards, we explored which variables had the most missing data and investigated whether data was randomly or non-randomly missing (see Table 1 in the appendix). We discovered that there was no data for se004, q121, and q028 from Mainland China and no data on respondent age from Mongolia.

After visualizing the breakdown of responses to our variable of interest by age group (table 2), we determined that age was unlikely to be a significant predictor in our final model. Due to the missing data, we decided to drop se004, q121, q028, and se003a from our dataset.

After visualizing our variable of interest (Graph 1), we determined that there were a good number of observations for each category of our response variable. This allowed us to proceed with putting together a multinomial lasso model.

Proposed Methodology:

What are the main method(s) that you are using and why? Be sure to choose methods that are statistically appropriate for the data. State any assumptions and why they are valid.

Analysis:

Analyze your data and provide evaluations. What do you find (include visualization if helpful).

We decided to transform our response variable q106 into two different categories. “Much worse,” “Somewhat worse,” “Much the same,” were encoded as 0, and “Somewhat better,”Much better than before" were encoded as 1. As a result, our goal is to predict if trends in the equal treatment of citizens has gotten worse/stayed the same, or gotten better. We decided to drop all NA’s from the dataframe. We considered using KNN to impute missing values, but we thought the missing data may have a systematic pattern, as seen in Table 5 in Appendix. We then decided to fit a lasso regression in order to decrease the variance of our model and also perform variable selection.

Conclusion:

What can you conclude from your analysis and how is this useful regarding the motivating question.

Appendix

Table 1 - table of missing values

```
##  [1]    8 3201   46  958 1184    0 1266  730  742  889 1231  904 1033   70 1829
